

NVIDIA RTX SPARK

Windows on Arm gets serious about graphics and local AI

Mithun Mohandas | editor@digit.in

Windows on Arm has spent years trying to answer a straightforward question: can a laptop move away from x86 without making familiar software feel like a compromise? Qualcomm certainly has put in a lot of efforts into making this a reality with their Snapdragon X and X2 platform. NVIDIA's RTX Spark adds another question. Can that same laptop also deliver the graphics capabilities, creative application acceleration and local AI capacity associated with an RTX machine?

Looks like we have an answer, even though it might be an early one. The ASUS ProArt P16 H7607BA is part of a new wave of devices that's poised to bring a sea change in the PC ecosystem. Its RTX Spark N1X combines a 20-core Arm CPU, Blackwell RTX graphics with 6,144 CUDA cores, and 64 GB of unified memory in the configuration assessed here. It runs Windows 11 Pro, supports NVIDIA's CUDA ecosystem and brings the familiar RTX feature set into a different processor and memory architecture. If all this seems familiar, then yes, it's pretty much everything that was present in one of NVIDIA's DGX Spark put together for Windows. Just that the DGX Spark had a much higher TDP whereas the RTX Spark machines are mostly limited to 80 Watts.

The combination of an NVIDIA CPU and GPU isn't just about slapping on another AI badge on a laptop. Conventional creator machines usually divide their resources between system RAM and a separate graphics memory pool. RTX Spark offers an alternative in which the CPU and GPU can access a large shared memory capacity. Similar to what Apple does with their unified memory approach for the Macbooks and the Mac Minis. For local models, complex scenes and certain creative projects, fitting the workload into memory can be as consequential as the speed of the processor executing it.

The results suggest that NVIDIA has built a credible high-performance Windows platform. They also show why its strongest argument is the combination of capabilities. RTX Spark does not lead every CPU benchmark, and a large memory pool does not automatically make it faster than a powerful discrete GPU. Its appeal lies in bringing useful CPU performance, RTX graphics and substantial local AI capacity together in a portable system.

A Windows platform

ASUS, like many other OEMs, announced its RTX Spark ProArt systems at Computex on 1 June 2026,
