

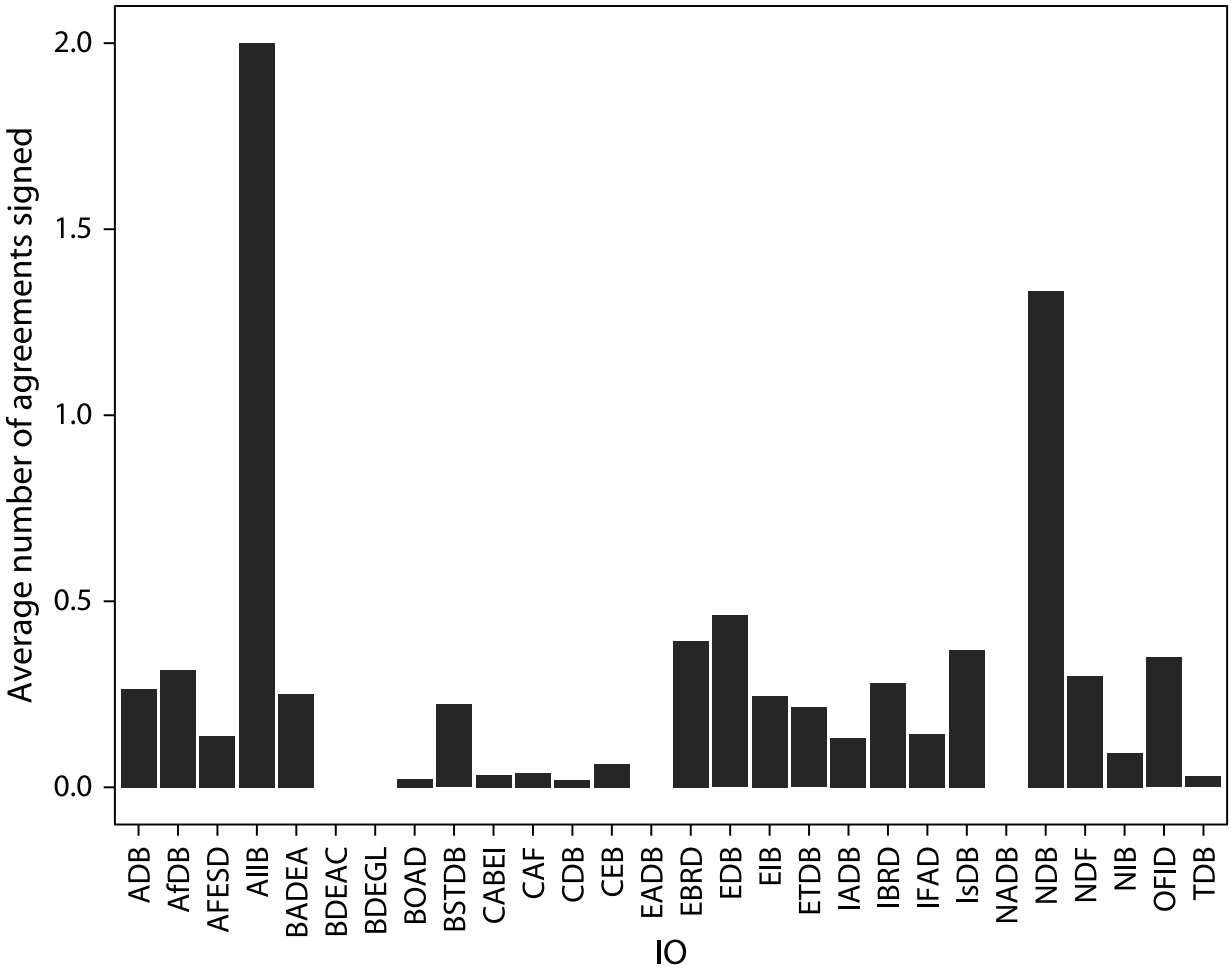

FIGURE 4.3. Average number of information-sharing agreements signed by IOs.

To test our theoretical claims, we analyze dyadic data between pairs of development IOs. To test our claims, we conduct an analysis using dyadic IO-level data. We specifically examine dyads with substantive and geographic overlap (i.e., those that perform similar functions and have overlapping memberships). Only such IO pairs should cooperate (Clark 2021). There are just over 5,700 dyads of overlapping development IOs in our data.

Our primary variable of interest is whether the leading stakeholder in each IO is governed by a populist leader. Leading stakeholders are identified based on voting power within the organization, supplemented by the influence of positions like IO president or managing director in cases of ties.[16] This measure varies between 0–2 (zero if neither most powerful state
