Note: Standard errors are clustered at the tweet-level. Model type is OLS. Author-fixed effects refers to author of the initial tweet. We subset here to retweets from elite actors, coded as those that are verified or that have at least 1,000 followers.
***p <.01; **p <.05; *p <.1

To limit the influence of preexisting knowledge and biases about IOs, we introduced a hypothetical development organization, the International Development Fund. Our approach also builds on recent work highlighting the potential benefits of abstraction in survey design (Brutger et al. 2022).

The control group received the following neutral description of the IDF's mission: "The International Development Fund (IDF) is an organization of 190 countries, working with developing countries to reduce poverty and achieve sustainable growth by financing investment, mobilizing capital in international financial markets, and providing advisory services to businesses and governments." This description was modeled closely on the missions of influential development IOs like the World Bank and the African Development Bank.

Respondents in the treatment conditions received one of two additional statements attributed to the fictional IDF president. In addition to the neutral description, those receiving the populist-style treatment were given the following text: "As someone who grew up with few resources or connections, I understand the struggles of the common people. I will make sure they prosper by working with them directly, providing them with crucial public services, and ensuring that wealthy elites do not take advantage of them." Those receiving the elite-style treatment saw this text: "The IDF is staffed by the world's best and most highly educated economists. These experts will ensure that the organization advances development and reduces poverty by efficiently allocating resources to spark economic growth."
