

Build RAG for Your AI's Memory

Turn private documents into answers your model can verify

A local language model can explain the history of computing yet know nothing about the repair policy you approved yesterday. Give it a folder containing that policy and a hundred other documents, and the problem does not automatically disappear. A model does not search folders simply because they exist beside it. We have to build the bridge between a question and the information needed to answer it.

That bridge is retrieval-augmented generation, or RAG. It is among the most practical ways to customise open AI because the source documents remain outside the model. You can replace an outdated policy without retraining anything, inspect which passages informed an answer and keep sensitive material on equipment you control. It also makes failures easier to investigate.

Knowledge isn't Memory

Here, "memory" means knowing where to look. Technically, RAG is retrieval, not a permanent alteration of the model's weights. Conversation memory is different again; it stores what users and applications decided during earlier interactions.

Imagine three questions. "What does warranty mean?" can be answered using general model knowledge. "What is our cur-
