

Fine-Tune Your Own Model

Teach a small model specialised skills without retraining everything

A model that answers questions competently may still be terrible at your particular job. Ask it to turn a messy customer complaint into a precisely formatted support ticket and it adds pleasantries. Ask for a three-line product brief and it produces five paragraphs. Explain the rules again, and it obeys them—until the next complicated input arrives. Fine-tuning is one way of making a preferred behaviour more reliable without rebuilding a language model from scratch.

The important qualification is that fine-tuning is not a magic upload button. It does not transform a tiny model into the smartest model available, and it is rarely the best way to teach a changing price list or a current policy. Done carelessly, it can teach mistakes more efficiently than it teaches skills. Our goal is a modest, measurable experiment: take an existing instruction-tuned model, train a compact adapter using examples of the output we want, and compare its answers with those of the unchanged model.
