

Table 2-2 Elementary Particles.

In addition to the baryons the other particles which are involved in the nuclear interaction are called *mesons.* There are first the pions, which come in three varieties, positive, negative, and neutral; they form another multiplet. We have also found some new things called K-mesons, and they occur as a doublet, K^+ and K^0. Also, every particle has its antiparticle, unless a particle *is its own* antiparticle. For example, the π—and the π+ are antiparticles, but the π^0 is its own antiparticle. The $K^{—}$ and K^+ are antiparticles, and the K^0 and K^0. In addition, in 1961 we also found some more mesons or *maybe* mesons which disintegrate almost immediately. A thing called ω which goes into three pions has a mass 780 on this scale, and somewhat less certain is an object which disintegrates into two pions. These particles, called mesons and baryons, and the antiparticles of the mesons are on the same chart, but the antiparticles of the baryons must be put on another chart, “reflected” through
