inhabiting distant parts of the world and living under considerably different conditions of life, yet often retaining nearly the same instincts. For instance, we c understand, on the principle of inheritance, how it is that t thrush of tropical South America lines its nest with mud, the same peculiar manner as does our British thrush; how it that the Hornbills of Africa and India have the same extraordi nary instinct of plastering up and imprisoning the females in hole in a tree, with only a small hole left in the plaster throu which the males feed them and their young when hatched; he it is that the male wrens (Troglodytes) of North America bu “cock-nests,” to roost in, like the males of our Kitty-wrens, a habit wholly unlike that of any other known bird. Finally, may not be a logical deduction, but to my imagination it is more satisfactory to look at such instincts as the young cuck ejecting its foster-brothers,—ants making slaves,—the larvæ ichneumonidæ feeding within the live bodies of caterpillars, not as specially endowed or created instincts, but as small cc sequences of one general law leading to the advancement all organic beings, —namely, multiply, vary, let the stronge live and the weakest die.
