Google upgrades its agent development kit

Google has introduced ADK (agent development kit) 2.0 – a major open source multi-agent framework designed to build, evaluate, debug and deploy AI agents and multi-agent systems. While being optimised for Google's Gemini models, it is model-agnostic and works with other language models as well as via LiteLLM.

ADK 2.0 shifts from a rigid, top-down hierarchy to a powerful graph-based execution engine, mixing deterministic code with adaptive AI. It officially supports Python and Go for its 2.0 graph architecture, alongside TypeScript for standard implementation. In ADK 1.x, agents operated under a strict hierarchical model. ADK 2.0 replaces this with a directed execution graph and reportedly provides dual orchestration.

ADK 2.0 also bundles a formal 'Task API' for structured agent-to-agent delegation. Instead of confusing back-and-forth prompts, you can implement a defined 'coordinator-plus-subagents' pattern that manages multi-turn tasks or single-turn controlled outputs cleanly.

As version 2.0 has completely rewritten the internal execution layer, upgrading requires caution. There are incompatibilities between versions, including storage (using ADK 2.0 code with ADK 1.x databases risks data loss) and event schema changes.

DeepSeek releases software tools for Huawei chips

DeepSeek has partnered with Huawei to develop software infrastructure for Ascend AI chips, while open sourcing components that support programming and distributed computing on the platform.

The release includes compute and communication libraries, along with an Ascend version of TileLang, a high-level open source programming language designed for AI accelerator development. DeepSeek says the language can simplify

SpaceX-owned Cursor launches GitHub alternative

Cursor has launched Origin, an early-beta native code-hosting platform built into Cursor, challenging GitHub's position as the default Git-based infrastructure for developers building with artificial intelligence agents. Available to paid Pro, Teams and Enterprise users from August 17, Origin is opt-out by default.

The biggest concern is code custody. Cursor has not published Origin-specific terms covering data retention, training use, sub-processors, or code export and migration for repositories hosted natively on Origin. The issue is amplified by SpaceX completing its US$ 60 billion all-stock acquisition of Cursor on August 14, just three days before the launch. Cursor's existing privacy documentation does not clearly establish how code stored on Origin is governed.

Origin retains standard Git workflows, including push/pull, pull requests, code browsing, GitHub mirroring with bidirectional synchronisation and integrations with Vercel, Depot and Buildkite. Its architecture uses NVMe-backed Git file servers with Amazon S3 as the source of truth. Cursor claims 22.6 commits per second, 296,000 clones per hour and under 400ms global synchronisation latency, although these figures are not independently verified in production.

The platform is designed around AI agents, offering automated merge-conflict resolution, failed-CI handling and pull-request generation.
