memQ open sources distributed quantum compiler

memQ has open sourced its Extensible Distributed Quantum Compiler (xDQC), which is designed to help quantum applications run across multiple quantum processing units (QPUs) instead of depending on a single quantum processor. Built on Nvidia's open source CUDA-Q platform, xDQC is intended to simplify the development of distributed quantum applications while allowing researchers to scale beyond the limits of individual QPUs.

Unlike conventional quantum compilers that target a single processor, xDQC partitions a quantum circuit across multiple QPUs and manages communication between them. It automatically handles qubit allocation, schedules operations across different processors and coordinates entanglement resources required for distributed execution, reducing the amount of manual optimisation needed when developing large quantum workloads.

The project is designed as an extensible framework rather than a fixed compiler implementation. Developers can adapt it to different quantum hardware configurations as distributed quantum computing evolves, making it suitable for research into multi-QPU architectures and future quantum-networked systems.

By releasing xDQC as open source software, memQ is making distributed quantum compilation more accessible to researchers and developers working on next-generation quantum infrastructure.

programming compared with lower-level approaches such as Nvidia's CUDA, while still allowing developers to optimise workloads for the hardware. The Ascend version wraps the platform's low-level Ascend C instructions, and DeepSeek says its training operators now have high-performance Ascend implementations.

The open source release also covers computing and distributed communication libraries for Huawei's Ascend platform. DeepSeek said the components correspond to versions it has previously released for Nvidia hardware, giving developers a software path for adapting AI workloads to Ascend-based systems. This adds to the growing open source software ecosystem around Huawei's AI processors.

Rather than replacing CUDA directly, the combination of TileLang and Ascend software provides another programming stack for AI accelerators and supports DeepSeek and Huawei's efforts to develop a more open, hardware-specific software ecosystem.

AI slop forces Google to suspend its vulnerability reward programme

A rise in low-quality, AI-generated vulnerability reports has driven Google to temporarily halt submissions for its Open Source Software Vulnerability Reward Programme (OSS VRP). Security engineers and maintainers were overwhelmed by the influx of invalid filings, prompting the company to announce an operational freeze on X and on the programme's website. Google plans to spend this hiatus redesigning its reporting framework and expects to share a progress update in Q1 2027.

The suspension took effect on October 1, though essential security pathways remain active. Valid product submissions filed before October 1 continue to be processed. Disclosures focused on supply chain vulnerabilities under the OSS VRP remain open. Researchers are being redirected towards Google's other active bug bounty initiatives.

This decision reflects a broader industry strain caused by automated AI spamming tools. Linux maintainers recently faced an overwhelming wave of bogus common vulnerabilities and exposures (CVE) submissions, peaking at 2000 recorded flaws per release, which ultimately forced the project to abandon support for legacy network drivers.

CERN pivoting away 2200 computers from Red Hat to Debian

At MiniDebConf Winterthur 2026 held in Switzerland, Conseil Européen pour la Recherche Nucléaire/European Organisation for Nuclear Research (CERN) engineers Federico Vaga and Nikos Tsipinakis detailed the plan for migrating over
