Ensuring Secure and Responsible AI with SAIF

The Secure AI Framework (SAIF) gives organisations a practical foundation for building secure and governable AI systems.

Artificial intelligence is used today to automate operations, support customer engagement, improve engineering productivity, detect cyber threats, personalise services, and generate business insights at scale. This rapid adoption creates enormous value, but it also introduces new risks that traditional IT governance models were not designed to manage. Models can be manipulated through malicious prompts, sensitive data may leak through outputs, training data can be poisoned, and autonomous agents may perform unintended actions if controls are weak. The Secure AI Framework, commonly known as SAIF, provides a practical way to address these challenges by extending proven security principles into the AI lifecycle.

SAIF was introduced by Google as a conceptual framework for securing AI systems and is built around the idea that AI should be secure by default, resilient by design, and governed throughout its lifecycle. The framework is not limited to a single technology stack or cloud platform. Instead, it offers a structured security and governance lens that organisations can apply across data,
