

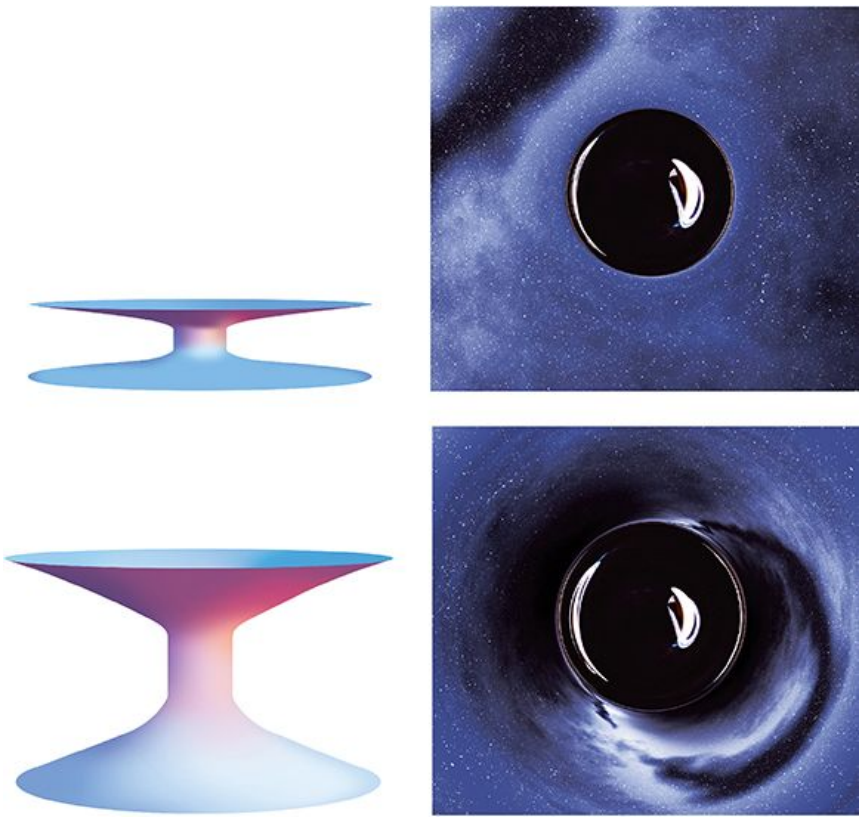

Fig. 15.4. Wormhole's gravitational lensing of a star field and Saturn: influence of the lensing width which is 0.014 and 0.43 times the wormhole radius in the top and bottom images. *[From simulations by Eugénie von Tunzelmann's team using Oliver James' code based on my equations.]*

Interstellar's Wormhole

When Chris saw the various possibilities, with varying wormhole length and lensing width, his choice was unequivocal. For medium and large length the multiple images seen through the wormhole would be confusing to a mass audience, so he made *Interstellar*'s wormhole very short: 1 percent of the wormhole radius. And he gave *Interstellar*'s wormhole a modest lensing width, about 5 percent of the wormhole radius, so the lensing of stars around it would be noticeable and intriguing, but much smaller than Gargantua's lensing.
