Now let's take every appearance of "camera" in the above discussion and replace it with "you." Rather than taking a picture with a mechanical apparatus, we (fancifully) imagine that you have really good eyesight and can see where electrons are just by looking at them. Otherwise, nothing changes. According to the Schrödinger equation, an initially unentangled situation—the electron is in a superposition of various possible locations, and you haven't looked at the electron yet—evolves smoothly into an entangled one—a superposition of each location the electron could have been observed, and you having seen the electron in just that location.

That's what the rules of quantum mechanics would say, if we hadn't tacked on all of those extra annoying bits about the measurement process. Maybe all of those extra rules were just a waste of time. In AQM, the story we just told, about you and the electron entangling and evolving into a superposition, is the complete story. There isn't anything special about measurement; it's just something that happens when two systems interact in an appropriate way. And afterward, *you and the system you interacted with are in a superposition*, in each part of which you have seen the electron in a slightly different location.

The problem is, this story still doesn't match onto what you actually experience when you observe a quantum system. You never feel like you have evolved into a superposition of different possible measurement outcomes; you simply think you've seen some specific outcome, which can be predicted with a definite probability. That's why all of those extra measurement rules were added in the first place. Otherwise you seemingly have a very pretty and elegant formalism (quantum states, smooth evolution) that just doesn't match up to reality.

Time to get a little philosophical. What exactly do we mean by "you" in the above paragraph? Constructing a scientific theory isn't simply a matter of writing down some equations; we also need to indicate how those equations map onto the world. When it comes to you and me, we tend to think that the process of matching ourselves onto some part of a scientific formalism is pretty straightforward. Certainly in the story told above, where an observer measures the position of an electron, it definitely seems as if that observer
